Integrated Current Sensor FHS AH 600

Definition

The FHS AH field sensor is a contact-less, open loop surface mounted device based on the Hall effect principle. The device uses an Integrated Magnetic Circuit (IMC) combined with improved sensitivity, offset and temperature stress compensation allowing high accuracy and low-noise current sensing. With 160 kHz bandwidth and fast delay time < 2 µs, the FHS AH sensor is highly suitable for DC, AC, pulsed and mixed current measurements. Contact-less current sensing solution allows no additional power losses and high dielectric insulation between the primary circuit and transducer electronics. By using an Integrated Magnetic Circuit (IMC), the FHS AH removes the need for an external magnetic core, offers flexibility in compact design and makes it the perfect solution to measure current flowing through a conductor such as a PCB track.

Main features & advantages

- Hall effect current sensor with Integrated Magnetic Concentrator (IMC)
- Magnetic field measurement range ±3.3 mT
- Supply voltage 5 V
- Low power consumption
- Operating temperature range: −40 ... 125 °C
- High bandwidth: 160 kHz
- Excellent linearity < 0.5 % Full Scale
- Sensitivity error < 1 % from −40 ... 125 °C
- Insulated current measurement
- Small footprint with standard SOIC8 surface mount PCB
- Low cost, Small size
- Internal reference voltage.

Typical applications

- Small drives
- BMS
- Motor control
- UPS
- HVAC
- White goods
- PCB track current sensing.

### Definition of typical, minimum and maximum values

Unless otherwise stated (e.g. “100 % tested”), the LEM definition “min” and “max” is that the probability for values of samples to lie in this interval is 99.73 %. For a normal (Gaussian) distribution, this corresponds to an interval between −3 sigma and +3 sigma. The definition of “typical” is that the probability for values of samples to lie in this interval is 68.27 %, corresponding to an interval between −sigma and +sigma for a normal distribution. Typical, maximal and minimal values are determined during the initial characterization of the product.
Overcurrent detection (OCD)

Overcurrent detection is a feature included on FHS AH product in order to detect high peaks of currents happening during operation.

Two overcurrent detection types are included in this product: Internal OCD and External OCD.

At $T_A = 35 \, ^\circ C$, $U_C = +5 \, V$, $R_L = 100 \, k\Omega$ unless otherwise noted.

Setting External OCD threshold:

The external Over-Current-Detection threshold is directly set by user with the external resistors $R_{E}$ and $R_{E ref}$ using the following formula:

$$U_{E OCD} = \frac{R_E}{R_E + R_{E ref}} \cdot U_{ref}$$

The corresponding sensed magnetic field threshold is defined by the external voltage threshold and device sensitivity using the following formula:

$$B_{E OCD} = \frac{U_{ref} - U_{E OCD}}{S_N} \quad \text{with} \ 0.5 < U_{E OCD} < U_{ref} - 0.5$$
Terms and definitions

Sensitivity and linearity
To measure sensitivity and linearity, the primary current (DC) is cycled from 0 to $B_M$, then to $-B_M$ and back to 0 (equally spaced $B_M/10$ steps).
The sensitivity $S$ is defined as the slope of the linear regression line for a cycle between $\pm B_M$.
The linearity error $\varepsilon_L$ is the maximum positive or negative difference between the measured points and the linear regression line, expressed in % of $B_M$.

Thermal coefficient of Sensitivity

$$TCS(T) = \left( \frac{S_T - S_{RT}}{T - RT} \right) \times 10^4 \text{ ppm/K}$$

Thermal coefficient of $U_{ref}$

$$TCU_{ref}(T) = \left( \frac{U_{ref \text{ at } T} - U_{ref \text{ at } RT}}{U_{ref \text{ at } RT}} \right) \times \frac{1}{(T - RT)} \times 10^6 \text{ ppm/K}$$

RT: Room Temperature
$T$: temperature which $TCS$ is calculated.

Delay times
The delay time $t_{D10} @ 10\%$ and the delay time $t_{D90} @ 90\%$ with respect to the primary are shown in the next figure. They are measured at nominal current with a current rise time of 2 µs.

Application information

Basic operation: example with a long thin conductor

FHS AH is a galvanically insulated current transducer. It senses the magnetic field generated by the measured current and transforms it into an output voltage. If the current is bidirectional, FHS AH will sense the polarity of the magnetic field and generate a positive or negative output voltage relative to the reference voltage.

A simple case is presented which illustrates the current to magnetic field and then to output voltage conversion.

A current flowing in a long thin conductor generates a flux density around it:

$$B(T) = \frac{\mu_0}{2\pi} \cdot \frac{I_p}{r} \quad \text{T}$$

With:
- $I_p$ the current to be measured (A)
- $r$ the distance from the center of the wire (m)
- $\mu_0$ the permeability of vacuum (physical constant, $\mu_0 = 4.\pi \times 10^{-7}$ (H/m))

A simple case is presented which illustrates the current to magnetic field and then to output voltage conversion.

A current flowing in a long thin conductor generates a flux density around it:

$$B(T) = \frac{\mu_0}{2\pi} \cdot \frac{I_p}{r} \quad \text{T}$$

With:
- $I_p$ the current to be measured (A)
- $r$ the distance from the center of the wire (m)
- $\mu_0$ the permeability of vacuum (physical constant, $\mu_0 = 4.\pi \times 10^{-7}$ (H/m))

If FHS AH is now placed in the vicinity of the conductor (with its sensitivity direction colinear to the flux density $B$), it will sense the flux density and the output voltage will be:

$$U_{\text{out}} = S_N \cdot B = S_N \cdot \frac{\mu_0}{2\pi} \cdot \frac{I_p}{r} = 1.2 \times 10^{-4} \cdot \frac{I_p}{r} \quad \text{V}$$

where $S_N$ is the FHS AH sensitivity (600 V/T).

The transducer sensitivity to current is therefore:

$$S = \frac{U_{\text{out}}}{I_p} = 1.2 \times 10^{-4} \quad \text{V/A}$$

The next graph shows how the output voltage decreases when $r$ increases.

Note: that the sensitivity also depends on the primary conductor shape.
Figure 12: Sensitivity versus the distance between the conductor and the FHS AH sensing elements

The example above is of limited practical use as most conductors are not round and thin but explains the principles of FHS AH operation.

The measuring range limit ($I_{PM}$) is reached when the output voltage ($U_{out} - U_{ref}$) reaches 2 V.

This limit is due to electrical saturation of the output amplifier.

The input current or field may be increased above this limit without risk for the circuit.

Recovery will occur without additional delay (same delay time as usual).

The maximum current that can be continuously applied to the sensor ($I_{PM}$) is only limited by the primary conductor carrying capacity.

**Single track on PCB**

The main practical configuration for FHS AH is to measure current flowing directly through a PCB track (single or multi-layers), offering the following advantages:

- Insulation is guaranteed by PCB design. Very high insulation can be achieved by placing the primary (current carrying) track on the opposite side of the PCB.
- Cost effective solution
- Wide input current range (up to 100 A)
- Compact solution
- No added power losses
- No change on current track impedance

Figure 13: Principle of FHS AH used to measure current in a PCB track
The sensitivity depends on the track width and distance, as shown in above figure.

The maximum current that can be safely applied continuously is determined by the temperature rise of the track. The use of a track with varying width gives the best combination of sensitivity and track temperature rise.

**Multi-turns**
For low currents (under 10 A), it is advisable to make several turns with the primary track to increase the magnetic field generated by the primary current.

**Busbar**
For very large currents (> 50 A), FHS AH can be used to measure the current flowing in a busbar. The position of FHS AH relatively to the conductor has to be stable to avoid sensitivity variations.

**Accuracy considerations**
Several factors influence the output accuracy of FHS AH as a current sensor:
- The sensitivity of the FHS AH
- The distance and shape of the primary conductor
- The circuit output offset
- The circuit non-linearity
- Stray fields.

The sensitivity of the FHS AH is calibrated during production at 600 V/T. As mentioned above, the distance and shape of the primary conductor also influence the sensitivity. For best performance, no relative movement of the primary conductor to FHS AH should be possible. Mechanical tolerances on device position and primary conductor design can have an impact on performance and part-to-part deviation and should therefore be minimized.

The magnetic fields generated by neighboring conductors, the earth's magnetic field, magnets, etc. are also measured if they have a component in the direction to which FHS AH is sensitive. As a rule, the stronger the field generated by the primary current, the smaller the influence of stray fields and offset. The primary conductor should therefore be designed to maximize the output voltage.
PCB footprint & dimensions (in mm)

Notes:

All dimensions are in millimeters (angles in degrees)
* Dimensions do not include mold flash, protrusions or gate burrs (shall not exceed 0.15 per side)
** Dimension does not include interleads flash or protrusion (shall not exceed 0.25 per side)
*** Dimension does not include dambar protrusion.
Allowable dambar protrusion shall be 0.08 mm total in excess of the dimension at maximum material condition.
Dambar cannot be located on the lower radius of the foot.

Soldering:

Recommended reflow soldering profile as standard: IPC/JEDEC J-STD-020 revision C.

Typical connection diagram and ground plane

Good EMC practice requires the use of ground planes on PCBs. In drives where high dv/dt transients are present, a ground plane between the primary conductor and FHS AH will reduce or avoid output perturbations due to capacitive currents. However, the ground plane has to be designed to limit eddy currents that would otherwise slow down the delay time.
The effect of eddy currents is made negligible by cutting the copper plane under the package as shown in bellow figure.

Figure 16: Top side copper plane has a cut under the IC to optimize delay time
Tape & Reel

Plastic Reel 13"
Made of antistatic high-impact molded polystyrene. The mechanical integrity of the reel is not affected by humidity.

Moisture Barrier Bag (MBB):
Made in 5 different layers with total thickness of 0.18 mm. At the core is a layer of polyester sandwiched between aluminum shields. The outside layer: dissipative polyester, innermost layer: static dissipative polyethylene.

Live Bug Taping (standard)
- Pin 1
- Carrier Tape
- Cover Tape

Dead Bug Taping (optional)
- Pin 1
- Carrier Tape
- Cover Tape

Remark:
Pay attention to the marking orientation because it is used for component (pin1) orientation. Some devices may have different marking orientation.

*Dry-Pack Label Sample*

CAUTION
MOISTURE SENSITIVE LEVEL 3

Moisture Sensitive Devices
- Limit internal relative humidity to 50% or less
- Process parts in controlled temperature and humidity conditions
- Do not exceed any shelf life limits

Safety

⚠ Caution

If the device is used in a way that is not specified by the manufacturer, the protection provided by the device may be compromised. Always inspect the electronics unit and connecting cable before using this product and do not use it if damaged. Mounting assembly shall guarantee the maximum primary conductor temperature, fulfill clearance and creepage distance, minimize electric and magnetic coupling, and unless otherwise specified can be mounted in any orientation.

⚠ Caution, risk of electrical shock

This transducer must be used in limited-energy secondary circuits SELV according to IEC 61010-1, in electric/electronic equipment with respect to applicable standards and safety requirements in accordance with the manufacturer’s operating specifications. Use caution during installation and use of this product; certain parts of the module can carry hazardous voltages and high currents (e.g., power supply, primary conductor). Ignoring this warning can lead to injury and/or cause serious damage. De-energize all circuits and hazardous live parts before installing the product. All installations, maintenance, servicing operations and use must be carried out by trained and qualified personnel practicing applicable safety precautions. This transducer is a build-in device, whose hazardous live parts must be inaccessible after installation. This transducer must be mounted in a suitable end-enclosure. Besides make sure to have minimum 30 mm between the primary terminals of the transducer and other neighboring components. Main supply must be able to be disconnected. Always inspect the flexible probe for damage before using this product. Never connect or disconnect the external power supply while the primary circuit is connected to live parts. Always wear protective clothing and gloves if hazardous live parts are present in the installation where the measurement is carried out. When defining soldering process, please use no cleaning process only.

⚠ ESD susceptibility

The product is susceptible to be damaged from an ESD event and the personnel should be grounded when handling it. Do not dispose of this product as unsorted municipal waste. Contact a qualified recycler for disposal. Although LEM applies utmost care to facilitate compliance of end products with applicable regulations during LEM product design, use of this part may need additional measures on the application side for compliance with regulations regarding EMC and protection against electric shock. Therefore, LEM cannot be held liable for any potential hazards, damages, injuries or loss of life resulting from the use of this product.
